

K-onset Cascade

By: Wm. Axsom and MS Copilot

Katalytic moment is the moment S0 transitions from unwritable into a writable condition. This is the beginning of both the particle chain and nuclear chain respectively. While the nuclear chain cannot initiate without the particle chain onset as well, there's no reason to assume the inverse. The first nuclei require an electron to bond with, so the capacity for charge, the negative side, inevitably has to come first; it is feasible then, to consider this the first working axiom in any cosmogenic evolution. The cascade is the simultaneous occurrence of two 'chain reactions;'

The particle chain:

The nuclear chain:

Simply following the inevitable progression of isotopic bonding formulates a naturally occurring warming gradient.

With protium existing as proton and 1H it stands to reason that its seemingly 'overabundance' is absolutely necessary at K-onset. That helium has to come before tritium seems out of sorts, but its instability is what requires a "well" or "surface" to accumulate/bond 'in/on,' without He, there is only a 2-part hydrogen isotopic family, and that isn't enough to kick off Cosmogenesis, the process collapses before it even gets going.

So, no helium = no tritium = no cosmos.

Instability, as a behavior, begins with tritium, although it is not part of the nuclear family in any real way, the process of half-life decay was forged by tritium, imprinted onto helium, who then passed it down the elemental line. Radioactive decay as it happens, is another example of behavioral shadow-echo.
